- Background. The number of individuals of each species in a given location forms the basis for many sub-fields of ecology and evolution. Data on individuals, including which species, and where they're found can be used for a large number of research questions. Global Biodiversity Information Facility (hereafter, GBIF) is the largest of these. Programmatic clients for GBIF would make research dealing with GBIF data
- Methods. We have developed clients to access GBIF data for each of the R, Python, and Ruby programming languages: rgbif, pygbif, gbifrb.
- 17 Results. For all clients we describe their design and utility, and demonstrate some use cases.

much easier and more reproducible.

Discussion. Programmatic access to GBIF will facilitate more open and reproducible science - the three GBIF clients described herein are a significant contribution towards this goal.

#### 8 Introduction

Perhaps the most fundamental element in many fields of ecology is the individual organism. The number 19 of individuals of each species in a given location forms the basis for many sub-fields of ecology and evolution. Some research questions necessitate collecting new data, while others can easily take advantage of existing data. In fact, some ecology fields are built largely on existing data, e.g., macro-ecology (Brown 1995; Beck et al. 2012). 23 Data on individuals, including which species, and where they're found, can be used for a large number 24 of research questions. Biodiversity records have been used for a suite of other use cases: validating habitat 25 suitability models with real occurrence data (Ficetola et al. 2014); ancestral range reconstruction (Ferretti et al. 2015; María Mendoza et al. 2015); development of invasive species watch lists (Faulkner et al. 2014); evaluating risk of invasive species spread (Febbraro et al. 2013); and effects of climate change on future biodiversity (Brown et al. 2015). In addition to wide utility, this data is important for conservation. Biodiversity loss is one of the greatest challenges of our time (Pimm et al. 2014), and some have called this the sixth great mass extinction (Ceballos et al. 2015). Given this challenge there is a great need for data on specimen records, whether collected from live sightings in the field or specimens in museums.

## 34 Global Biodiversity Information Facility

There are many online services that collect and maintain specimen records. However, Global Biodiversity
Information Facility (hereafter, GBIF, http://www.gbif.org) is the largest collection of biodiversity records
globally, currently with 820 million records, roughly 5.9 million taxa, 36,000 datasets from 1,300 publishers
(as of 2016-02-09). Many large biodiversity warehouses such as iNaturalist (http://www.inaturalist.org),
VertNet (http://vertnet.org), and USGS's Biodiversity Information Serving Our Nation (BISON; http://
bison.usgs.ornl.gov) all feed into GBIF.

The most important organizational level in GBIF occurrence data is the occurrence record. The fields in
a record vary, but include information about taxonomy (kingdom, phylum, genus, species names) and their
identifiers, dataset metadata, and locality information including geospatial position. Going upstream, each
record is part of a dataset, where each dataset is submitted by an organization, organizations are organized
into nodes, datasets are published through institutions (which may be hosted at another organization), and
a network is a group of datasets (managed by GBIF).

- Each occurrence record has some taxonomic name associated with it, which itself is linked to a lot of
- other taxonomic data including a master taxonomic backbone that integrates taxonomies across many
- 49 taxonomic authorities.
- $_{50}$  The organization of GBIF matters because you can navigate GBIF data through these hierarchical
- organizational levels it helps to be familiar with the terminology and how each group relates to another.

### 52 The clients

- Although we discuss libraries for R, Python, and Ruby here, we focus mostly on the R library rgbif as it has seen the most developer and user attention, and is the most mature.
- 55 rgbif
- Herein, we describe the rgbif software package (Chamberlain et al.) for working with GBIF data in
- 57 the R programming environment (R Core Team 2014). R is a widely used language in academia, as well
- as non-profit and private sectors. Importantly, R makes it easy to execute all steps of the research process,
- 59 including data management, data manipulation and cleaning, statistics, and visualization. Thus, an R client
- 60 for getting GBIF data is a powerful tool to facilitate reproducible research.
- The rgbif package is nearly completely written in R (a small Javascript library is included for reading
- 62 well known text (Herring 2011)), uses an MIT license to maximize use everywhere. rgbif is developed
- 63 publicly on GitHub at https://github.com/ropensci/rgbif, where development versions of the package can
- be installed, and bugs and feature requests reported. Stable versions of rgbif can be installed from CRAN,
- the distribution network for R packages. rgbif is part of the rOpenSci project (https://ropensci.org), a
- 66 developer network making R software to facilitate reproducible research.
- 67 pygbif
- pygbif (Chamberlain) is a Python library for working with GBIF data in the Python programming
- environment. Python is a general purpose programming language used widely in all sectors, and for all
- 70 parts of software development including server and client side use cases. Python is used exclusively in some
- scientific disciplines (e.g., astronomy), and has partial usage in other disciplines. A Python client for GBIF
- data is an important tool given the even wider usage of Python than R, though maybe slightly less than R
- <sub>73</sub> for ecology/biology disciplines.

#### pip install pygbif

## import pygbif

- The pygbif library is less mature and complete than the R package. It also uses an MIT license to maximize use everywhere. pygbif is developed publicly on GitHub at https://github.com/sckott/pygbif, where development versions of the package can be installed, and bugs and feature requests reported. Stable versions of pygbif can be installed from pypi, the distribution network for Python libraries.
- 78 gbifrb
- gbifrb (Chamberlain) is a library for working with GBIF data in the Ruby programming environment.
- blue Python, Ruby is a general purpose programming language used widely in all sectors. Unlike Python,
- 81 Ruby is not used extensively in scientific disciplines. However, a Ruby client for GBIF data can be an
- important tool given how widely Ruby is used for web and web service development.

#### gem install gbifrb

# require 'gbifrb'

- The gbifrb library is less mature and complete than the R and Python libraries. It also uses an MIT
- license to maximize use everywhere. gbifrb is developed publicly on GitHub at https://github.com/sckott/
- gbifrb, where development versions of the package can be installed, and bugs and feature requests reported.
- Stable versions of gbifrb can be installed from Rubygems, the distribution network for Ruby libraries.

## 87 Library interfaces

- rgbif, pygbif, and gbifrb are designed following the GBIF Application Programming Interface, or
- 89 API. The GBIF API has four major components: registry, taxonomic names, occurrences, and maps. We
- also include functions to interface with the OAI-PMH GBIF service; only dataset (registry) information is
- available via this service, however. An interface to the GBIF maps API is in development for rgbif, but
- 92 is non-existent for both pygbif and gbifrb. All three libraries have a suite of functions dealing with each
- of registry, taxonomic, names, and occurrences we'll go through each in turn describing design of the user
- 94 interface and example usage.

#### 95 GBIF headers

- With each request rgbif, pygbif, gbifrb make to GBIF's API, we send request headers that tell GBIF
- what library the request is coming from, including what version of the library. This helps GBIF know
- 98 what proportion of requests are coming from which library, and therefore from R vs. Python vs. Ruby; this
- 99 information is helpful for GBIF in thinking about how people are using GBIF data.

#### 100 Registry

- The GBIF registry API services are spread across five sets of functions via the main GBIF API:
- Datasets
- Installations
- Networks
- Nodes
- Organizations
- Dataset information in general is available via the OAI-PMH service, functions in rgbif prefixed with gbif\_oai\_, but not available in pygbif or gbifrb yet.
- Datasets are owned by organizations. Organizations are endorsed by nodes to share datasets with GBIF.
- Datasets are published through institutions, which may be hosted at another organization. A network is a
- group of datasets (managed by GBIF). Datasets are the units that matter the most with respect to registry
- information, while installations, networks, nodes, and organizations are simply higher level organizational
- 113 structure.

#### 114 Datasets

- Dataset functions include search, dataset metadata retrieval, and dataset metrics. Searching for datasets
- is an important part of the discovery process. One can search for datasets on the GBIF web portal. However,
- programmatic searching using any of these libraries is more powerful. Identifying datasets appropriate for
- a research question is helpful as you can get metadata for each dataset, and track down dataset specific
- problems, if any.
- The dataset\_search() function in rgbif is one way to search for datasets. Here, we search for the
- term "oregon", which finds any datasets that have words matching that term.

```
res <- dataset_search(query = "oregon")</pre>
res$data$datasetTitle[1:10]
    [1] "Oregon State Ichthyology Collection"
    [2] "Oregon State University Herpetological Collection"
#>
    [3] "Mygalomorph spiders from southwestern Oregon, USA, with descriptions of four new species"
    [4] "A new species of Helobdella (Hirudinida: Glossiphoniidae) from Oregon, USA"
    [5] "Cave millipedes of the United States. XVI. Two new species from Oregon Caves National Monumer
    [6] "Annotated Checklist of the large branchiopod crustaceans of Idaho, Oregon and Washington, USA
#>
    [7] "A new species of Chrysobothris Eschscholtz from Oregon and Washington, with notes on other Bo
#>
    [8] "Three new species of Grylloblatta Walker (Insecta: Grylloblattodea: Grylloblattidae), from se
#>
    [9] "A new species of Cladotanytarsus (Lenziella) from Oregon supports the systematic concept of
#> [10] "Two new species of Fluminicola (Caenogastropoda, Lithoglyphidae) from southwest Oregon, USA,
```

- See also datasets() and dataset\_suggest() in rgbif for searching for datasets.
- In Python, we can similarly search for datasets. Here, search for datasets of type OCCURRENCE:

```
from pygbif import registry
registry.datasets(type="OCCURRENCE")
```

In Ruby, we can do the same. Here, search for datasets of type OCCURRENCE:

```
require 'gbifrb'
registry = Gbif::Registry
registry.datasets(type: "OCCURRENCE")
```

125 Dataset metrics

124

- Dataset metrics are another useful way of figuring out what datasets you may want to use. One drawback is that these metrics data are only available for datasets of type *checklist*, but there are quite a lot of them (29853).
- Here, in R we search for dataset metrics for a single dataset, with uuid ec93a739-1681-4b04-b62f-3a687127a17f,
  a checklist of the ants (Hymenoptera: Formicidae) of the World.

rank	count
SPECIES	13710
SUBSPECIES	3234
GENUS	726
TRIBE	53
SUBFAMILY	20
FAMILY	2
KINGDOM	1
PHYLUM	1
CLASS	1
ORDER	1

And in Python, get metrics for the same dataset as above:

```
from pygbif import registry
registry.dataset_metrics(uuid='ec93a739-1681-4b04-b62f-3a687127a17f')
```

The same in Ruby:

```
require 'gbifrb'
registry = Gbif::Registry
registry.dataset_metrics(uuid: 'ec93a739-1681-4b04-b62f-3a687127a17f')
```

- Networks, nodes, and installations
- Networks, nodes and installations are at a higher level of organization above datasets, but can be useful if you want to explore data from given organizations. Here, in R we search for the first 10 GBIF networks, returning just the title field.

```
networks(limit = 10)$data$title
#> [1] "TrIAS"
#> [2] "Arctos"
#> [3] "Freshwater Network"
#> [4] "Ocean Biogeographic Information System (OBIS)"
   And in Python:
from pygbif import registry
registry.networks(limit = 10)
   And in Ruby:
require 'gbifrb'
registry = Gbif::Registry
registry.networks(limit: 10)
Taxonomic names
   The GBIF taxonomic names API services are spread across five functions in rgbif:
  • Search GBIF name backbone - name_backbone()
  • Search across all checklists - name_lookup()
  • Quick name lookup - name_suggest()
  • Name usage of a name according to a checklist - name_usage()
  • GBIF name parser - parsenames()
  pygbif and gbifrb have all the same functions, except the name parser goes by name_parser() in
pygbif and gbifrb.
   The goal of these name functions is often to settle on a taxonomic name known to GBIF's database.
This serves two purposes: 1) when referring to a taxonomic name, you can point to a URI on the Internet,
and 2) you can search for metadata on a taxon, and occurrences of that taxon in GBIF.
```

140

141

142

143

146

147

148

151

the same taxonomic names, and some taxonomic groups have preferred sources for the definitive names for

Taxonomic names are particularly tricky. Many different organizations have their own unique codes for

that group. That's why it's best to determine what name GBIF uses, and its associated identifier, for the taxon of interest instead of simply searching for occurrences with a taxonomic name.

When searching for occurrences (see below) you can search by taxonomic name (and other filters, e.g., taxonomic rank), but you're probably better off figuring out the taxonomic key in the GBIF backbone taxonomy, and using that to search for occurrences. The taxonkey parameter in the GBIF occurrences API expects a GBIF backbone taxon key.

#### 159 GBIF Backbone

The GBIF backbone taxonomy is used in GBIF to have a consistent way to refer to taxonomic names throughout their services. The backbone has 6575748 unique names and 2730631 species names. The backbone taxonomy is also a dataset with key d7dddbf4-2cf0-4f39-9b2a-bb099caae36c (https://www.gbif.org/dataset/d7dddbf4-2cf0-4f39-9b2a-bb099caae36c).

We can search the backbone taxonomy with the function name\_backbone() in all thee clients. Here,
we're searching for the name *Poa*, restricting to genera, and the family *Poaceae*, in R

```
res <- name_backbone(name='Poa', rank='genus', family='Poaceae')
res[c('usageKey', 'kingdom')]
#> # A tibble: 1 x 2
#> usageKey kingdom
#> <int> <chr>
#> 1 2704173 Plantae
```

And in Python

```
from pygbif import species

res = species.name_backbone(name='Poa', rank='genus', family='Poaceae')
[ res[x] for x in ['usageKey', 'kingdom'] ]
```

And in Ruby

```
require 'gbifrb'
species = Gbif::Species
res = species.name_backbone(name: 'Poa', rank: 'genus', family: 'Poaceae')
res.select { |k,v| k.match(/usageKey|kingdom/) }
```

- Name searching
- One of the quickest ways to search for names is using name\_suggest(), which does a very quick search and returns minimal data. Here, we're searching for the query term *Pum*, and we get back many names:

```
name_suggest(q='Pum', limit = 6)
```

key	canonicalName	rank
2142856	Althepus pum	SPECIES
8589398	Pumiliopimoidae	FAMILY
8608394	Pumiliopimoa	GENUS
4579844	Pumilibaxa	GENUS
4581745	Pumicia	GENUS
8783253	Pumililema	GENUS

The same in Python

```
from pygbif import species
species.name_suggest(q='Pum', limit = 6)
```

2 And in Ruby

```
require 'gbifrb'
species = Gbif::Species
species.name_suggest(q: 'Pum', limit: 6)
```

- With these results, you can then proceed to search for occurrences with the taxon key(s), or drill down further with other name searching functions to get the exact taxon of interest.
- Occurrences
- GBIF provides two ways to get occurrence data: through the /occurrence/search route (see occ\_search in rgbif, occurrences.search in pygbif, Occurrences.search in gbifrb), or via the /occurrence/download route (many functions, see below).

occ\_search()/occurrences.search/Occurrences.search are the main functions for the search route, and are more appropriate when you want less data, while the download functions are more appropriate for larger data requests.

Small vs. large amounts of data of course is all relative. GBIF imposes for any given search a limit of 200,000 records in the search service, after which point you can't download any more records for that search.

However, you can download more records for different searches.

We think the search service is still quite useful for many people even given the 200,000 limit. For those that need more data, we have created a similar interface in the download functions that should be easy to use with minimal work. Users should take note that using the download service has a few extra steps to get data into R, but is straight-forward.

The download service, like the occurrence search service, is rate-limited. That is, you can only have one to three downloads running simultaneously for your user credentials. However, simply check when a download job is complete, then you can start a new download request. See "Queuing Download Requests" below for help automating many download requests in R.

#### 193 Occurrences Download API

189

190

191

192

The download API syntax is similar to the occurrence search API in that the same parameters are used, but the way in which the query is defined is different. For example, in the download API you can do greater than searches (i.e., latitude > 50), whereas you cannot do that in the occurrence search API.

Thus, unfortunately, we couldn't make the query interface exactly the same for both search and download functions.

Using the download service can consist of as few as three steps: 1) Request data via a search; 2) Download data; 3) Import data into R.

Request data download given a query. Here, we search for the taxon key 3119195, which is the key for Helianthus annuus (http://www.gbif.org/species/3119195).

```
occ_download('taxonKey = 3119195')
#> <<gbif download>>
#> Username: xxxx
#> E-mail: xxxx
#> Download key: 0000840-150615163101818
```

- You can check on when the download is ready using the functions occ\_download\_list() and occ\_download\_meta().
- When it's ready use occ\_download\_get() to download the dataset to your computer.

```
(res <- occ_download_get("0000840-150615163101818", overwrite = TRUE))
#> <<gbif downloaded get>>
#> Path: ./0000840-150615163101818.zip
#> File size: 3.19 MB
```

- What's printed out above is a very brief summary of what was downloaded, the path to the file, and its size (in human readable form).
- Next, read the data in to R using the function occ\_download\_import().

#>

#>

#>

```
library("dplyr")

#### In Python

208

```
from pygbif import occurrences as occ
occ.download('taxonKey = 3119195')
(res = occ.download_get("0000840-150615163101818", overwrite = True))
```

- We don't have pygbif functionality at the moment for importing data, but it's coming soon.
- The Ruby library gbifrb does not yet have occurrence download functionality.

#### 211 Downloaded data format

The downloaded dataset from GBIF is a Darwin Core Archive (DwC-A), an internationally recognized biodiversity informatics standard (http://rs.tdwg.org/dwc/). The DwC-A downloaded is a compressed folder with a number of files, including metadata, citations for each of the datasets included in the download, and the data itself, in separate files for each dataset as well as one single .txt file. In rgbif::occ\_download\_import(), we simply fetch data from the .txt file. If you want to dig into the metadata, citations, etc., it is easily accessible from the folder on your computer.

## 218 Search API

The search API follows the GBIF API and is broken down into the following functions:

- Get a single numeric count of occurrences rgbif: occ\_count() / pygbif: occurrences.count / gbifrb: Occurrences.count
- Search for occurrences rgbif: occ\_search() / pygbif: occurrences.search / gbifrb: Occurrences.search
- A simplified and optimized version of rgbif: occ\_search() or occ\_data() / none / none
- Get occurrences by occurrence identifier rgbif: occ\_get() / pygbif: occurrences.get / gbifrb:

  Occurrences.get
- Get occurrence metadata rgbif: occ\_metadata() / pygbif: various / gbifrb: various

## 227 Search for occurrences

- The main search work-horse is occ\_search(). This function allows very flexible search definitions. In addition, this function does paging internally, making it such that the user does not have worry about the 300 records per request limit but of course we can't go over the 200,000 maximum limit.
- The output of occ\_search() presents a compact data.frame so that no matter how large the data.frame, the output is easily assessed because only a few of the records (rows) are shown, only a few columns are

- shown (with others shown in name only), and metadata is shown on top of the data.frame to indicate data
- 234 found and returned, media records found, unique taxonomic hierarchies returned, and the query executed.
- The output of these examples, except one, aren't shown.
- Search by species name, using name\_backbone() first to get key
- $\mathbf{R}$

```
library(rgbif)
(key <- name_suggest(q = 'Helianthus annuus', rank = 'species')$key[1])</pre>
#> [1] 9206251
occ_search(taxonKey = key, limit = 2)
#> Records found [46490]
#> Records returned [2]
#> No. unique hierarchies [1]
#> No. media records [2]
#> No. facets [0]
#> Args [limit=2, offset=0, taxonKey=9206251, fields=all]
#> # A tibble: 2 x 71

```

#### Python

```
from pygbif import species
from pygbif import occurrences as occ
key = species.name_suggest(q = 'Helianthus annuus', rank = 'species')['data'][0]['key']
occ.search(taxonKey = key, limit = 2)
```

```
Ruby
```

239

```
require 'gbifrb'
   species = Gbif::Species
   occ = Gbif::Occurrences
   key = species.name_suggest(q: 'Helianthus annuus', rank: 'species')['data'][0]['key']
   occ.search(taxonKey: key, limit: 2)
      Instead of getting a taxon key first, you can search for a name directly
240
      \mathbf{R}
   occ_search(scientificName = 'Ursus americanus')
      Python
   occ.search(scientificName = 'Ursus americanus')
      Ruby
   occ.search(scientificName: 'Ursus americanus')
      Search for many species
244
      \mathbf{R}
245
   splist <- c('Cyanocitta stelleri', 'Junco hyemalis', 'Aix sponsa')</pre>
   keys <- sapply(splist, function(x) name_suggest(x)$key[1], USE.NAMES = FALSE)</pre>
   occ_search(taxonKey = keys, limit = 5, return = 'data')
      Python
   from pygbif import species
   from pygbif import occurrences as occ
   splist = ['Cyanocitta stelleri', 'Junco hyemalis', 'Aix sponsa']
   keys = [ species.name_suggest(x)['data'][0]['key'] for x in splist ]
   occ.search(taxonKey = keys, limit = 5)
```

Ruby

```
species = Gbif::Species

occ = Gbif::Occurrences

splist = ['Cyanocitta stelleri', 'Junco hyemalis', 'Aix sponsa']

keys = [ species.name_suggest(x)['data'][0]['key'] for x in splist ]

occ.search(taxonKey: keys, limit: 5)
```

Spatial search, based on well known text format (Herring 2011), or a bounding box set of four coordinates. The well known text string and the bounding box in the below example specify the same rectangular area in California, centering approximately on Sacramento. Whereas the bounding box format requires longitude SW corner, latitude SW corner, longitude NE corner, latitude NE corner, the
well known text string requires an extra long/lat pair to close the polygon.

 $\mathbf{R}$ 

253

254

```
# well known text
wkt <- 'POLYGON((-122.6 39.9,-120.0 39.9,-120.0 37.9,-122.6 37.9,-122.6 39.9))'
occ_search(geometry = wkt, limit = 20)
# bounding box
occ_search(geometry = c(-122.6,37.9,-120.0,39.9), limit = 20)</pre>
```

# Python

```
from pygbif import occurrences as occ
# well known text
occ.search(geometry = 'POLYGON((30.1 10.1, 10 20, 20 40, 40 40, 30.1 10.1))', limit = 20)
# bounding box
occ.search(geometry = '-125.0,38.4,-121.8,40.9', limit = 20)
```

# Ruby

```
occ = Gbif::Occurrences
# well known text
occ.search(geometry: 'POLYGON((30.1 10.1, 10 20, 20 40, 40 40, 30.1 10.1))', limit: 20)
# bounding box
occ.search(geometry: '-125.0,38.4,-121.8,40.9', limit: 20)
```

Get only occurrences with lat/long data using the hasCoordinate parameter

 $\mathbf{R}$ 

```
occ_search(hasCoordinate = TRUE, limit = 5)
```

#### Python

```
from pygbif import occurrences as occ
occ.search(hasCoordinate = True, limit = 5)
```

#### Ruby

259

```
occ = Gbif::Occurrences
occ.search(hasCoordinate: true, limit: 5)
```

Get only those occurrences with spatial issues. Spatial issues are a set of issues that are returned in the issues field. They each indicate something different about that record. For example, the issue COUNTRY\_COORDINATE\_MISMATCH indicates that the interpreted occurrence coordinates fall outside of the indicated country. You can see how that might be useful when it comes to cleaning your data prior to analysis/visualization.

 $\mathbf{R}$ 

265

```
occ_search(hasGeospatialIssue = TRUE, limit = 5)
```

# Python

```
from pygbif import occurrences as occ
occ.search(hasGeospatialIssue = True, limit = 5)
```

## Ruby

```
occ = Gbif::Occurrences
occ.search(hasGeospatialIssue: true, limit: 5)
```

#### 268 Data cleaning

GBIF provides optional data issues with each occurrence record. These issues fall into many different predefined classes, covering issues with taxonomic names, geographic data, and more (see rgbif::occ\_issues\_lookup()

271 to find out more information on GBIF issues; and the same data on GBIF's development site).

rgbif::occ\_issues() provides a way to easily filter data downloaded via rgbif::occ\_search() based
on GBIF issues.

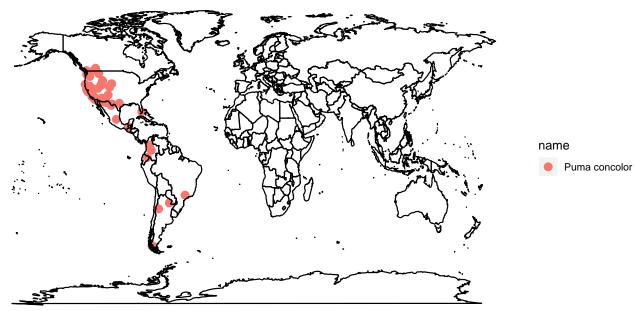

```
out <- occ_search(issue = 'DEPTH_UNLIKELY', limit = 500)
NROW(out)
#> [1] 5
out %>% occ_issues(-cudc) %>% .$data %>% NROW
#> [1] 500
```

There's no equivalent interface in pygbif or gbifrb yet.

# 275 Mapping

An obvious downstream use case for species occurrence data is to map the data. rgbif has enough to
do without handling mapping. Another package, mapr, works with rgbif to make this easy. For example,
here we plot 100 occurrences for *Puma concolor*.

```
library(mapr)
key <- name_backbone(name='Puma concolor')$speciesKey
dat <- occ_search(taxonKey = key, limit = 100, hasCoordinate = TRUE)
map_ggplot(dat, name = "species")</pre>
```

mapr has convenient functions for handling input data from rgbif, spocc, or arbitrary data.frame's, and output plots for base plots, ggplot2, ggmap (ggplot2 with map layers underneath), and interactive maps on GitHub gists or with Leaflet.js.

There's no equivalent interface in pygbif or gbifrb.

### 284 Citing GBIF data

293

All the data within GBIF was painstakingly collected by people and institutions across the globe. They
all, including GBIF, deserve to be cited appropropriately if you use any GBIF data in your research. There
are clear forces making this difficult however. Publishers often limit, without reason if the publication is
online only, the number of citations one can include a manuscript. Even when this happens, you can always
include additional citations in an appendix.

To make citing data from GBIF easier rgbif has a function gbif\_citation(), which accepts the output of many different rgbif functions and gives citations for each dataset represented in the data therein. For example, suppose you searched for occurrences for taxonKey 9206251 (Helianthus annuus):

```
res <- occ_search(taxonKey = 9206251, limit = 20)</pre>
```

We retrieved 20 occurrences from 4 different datasets.

To get citations for each of the four datasets, one can pass the output of occ\_search(), here the object res, to the gbif\_citation() function:

```
cites <- gbif_citation(res)
cites

- And we get four citations, one of each of the datasets behind the 20 occurrence records retrieved.
- We don't yet have the same functionality available in pygbif, but it will be coming soon.
- 298 Downloads vs. searches
- The distinction between "downloads" and "searches" is not especially meaningful with respect to the science done with GBIF data. However, downloads and searches are different with respect to easily being

able to cite GBIF data, which matters for GBIF and for data providers.

Downloads refers to the rgbif functions that start with occ\_download, and the pygbif methods that
start with occurrences.download. These methods use the GBIF "downloads API", which you can interact
with from rgbif and pygbif programatically, similar to how you would interact with the GBIF website each interaction creating a download request, which processes in the background. The user has to ask if the
request is ready to download. Downloads can request a very large amount of data.

Searches are faster and more dynamic. Search functions in rgbif include occ\_search, occ\_data, and occ\_get, while pygbif methods include occurrences.search, occurrences.get. These methods can only request up to 200,000 occurrence records.

The big difference between downloads and searches with respect to citations is that each download generates a Digital Object Identifier (or DOI). This DOI can be used cite the entire set of data, that can inlude many datasets. There's no good way to refer to the entire results of searches, other than the user manually creating a dataset somewhere public and linking to it from Zenodo to get a DOI. However, simply using downloads is simpler in terms of getting a single citeable DOI for the data used in a research paper/project.

In rgbif, the output of occ\_download\_meta() can be passed to gbif\_citation() to get the citation for the entire download.

```
key <- "0000122-171020152545675"

res <- occ_download_meta(key)

gbif_citation(res)

#> $download

#> [1] "GBIF Occurrence Download https://doi.org/10.15468/dl.yghxj7 Accessed from R via rgbif (https://doi.org/10.15468/dl.yghxj7 Accessed from
```

If you however download the data first, then gbif\_citation() can get citations for all the datasets contained within the download.

```
d1 <- occ_download_get(key, overwrite = TRUE)
gbif_citation(d1)
#> $download
```

```
#> [1] "GBIF Occurrence Download https://doi.org/10.15468/dl.yghxj7 Accessed from R via rgbif (https://

# GBIF data in other R packages

We discuss usage of GBIF data in other R packages throughout the manuscript, but provide a synopsis
here for clarity.

#### 323 taxize

Some of the GBIF taxonomic services are also available in taxize, an R package that focuses on getting
data from taxonomic data sources on the web. For example, with get\_gbifid() one can get GBIF IDs used
for a set of taxonomic names - then use those IDs in other functions in taxize to get additional information,
like taxonomically downstream children.

#### 328 *spocc*

GBIF occurrence data is available in the R package spocc via rgbif. spocc is a unified interface for fetching species occurrence data from many sources on the web. For example, a user can collect occurrence data from GBIF, iDigBio, and iNaturalist, and easily combine them, then use other packages to clean and visualize the data.

# R vs. Python vs. Ruby

Both R and Python are commonly used in science, and can be used for similar tasks. Python, however, is a more general programming language, and can be used in more contexts than R can be used in. Ruby is used very little in science; but, like Python, Ruby is very widely used as a general purpose programming language, with heavy use in web development and web services.

The three clients can do a lot of the same tasks. We envision rgbif being more common in workflows
of academics asking research questions, whereas pygbif and gbifrb can do that as well, but may be more
easily used in a website.

The R client rgbif has had much more development time than pygbif and gbifrb, but with time pygbif and gbifrb will become equally mature.

#### 343 Use cases

The following are three use cases for the R library rgbif: niche modeling, spatial change in biodiversity,
and distribution mapping.

# $Ecological\ niche\ modeling$

In this example, we plot actual occurrence data for *Bradypus* species against a single predictor variable,
BIO1 (annual mean temperature). This is only one step in a species distribution modelling workflow.

This example can be done using BISON data as well with our rbison package.

#### Load libraries

349

```
library("sp")
   library("rgbif")
   library("dismo")
   library("maptools")
   library("dplyr")
       Raster files
351
       Make a list of files that are installed with the dismo package, then create a rasterStack from these
352
   files <- list.files(paste(system.file(package = "dismo"), "/ex", sep = ""),
                          "grd", full.names = TRUE)
   predictors <- stack(files)</pre>
       Get world boundaries
   data(wrld_simpl)
       Get GBIF data using the rOpenSci package rgbif
   nn <- name_lookup("bradypus*", rank = "species")</pre>
   nn <- na.omit(unique(nn$data$nubKey))</pre>
   df <- occ_search(taxonKey = nn, hasCoordinate = TRUE, limit = 500)</pre>
   df_data <- df[ sapply(df, function(x) any(class(x$data) %in% "tbl_df")) ]</pre>
   df_data <- dplyr::bind_rows(lapply(df_data, "[[", "data"))</pre>
   df2 <- df_data %>% dplyr::select(decimalLongitude, decimalLatitude)
       Plot
355
     (1) Add raster data, (2) Add political boundaries, (3) Add the points (occurrences)
   plot(predictors, 1)
   plot(wrld_simpl, add = TRUE)
   points(df2, col = "blue")
```

# bio1 4 20 250 200 0 150 100 -2050 0 -40 -50 -150 -100 0

358 Biodiversity in big cities

In this example, we collect specimen records across different cities using GBIF data from the rgbif package.

Load libraries

357

```
library("rgbif")
library("ggplot2")
library("plyr")
library("httr")
library("RColorBrewer")
library("wicket")
```

Get bounding boxes for some cites

Bounding lat/long data is from https://raw.github.com/amyxzhang/boundingbox-cities/master/boundbox.

364 txt.

362

```
url <- 'https://raw.githubusercontent.com/amyxzhang/
boundingbox-cities/master/boundbox.txt'
rawdat <- content(GET(sub("\n", "", url)), as = "text")</pre>
```

```
dat <- read.table(
  text = rawdat, header = FALSE,
  sep = "\t", col.names = c("city", "minlat", "maxlon", "maxlat", "minlon"),
  stringsAsFactors = FALSE)
dat <- data.frame(
  city = dat$city, minlon = dat$minlon,
  minlat = dat$minlat, maxlon = dat$maxlon,
  maxlat = dat$maxlat,
  stringsAsFactors = FALSE
)</pre>
```

A helper function to get count data. GBIF has a count API, but we can't use that with a geometry search as that API doesn't support geospatial search. We can however use the search API via occ\_search() and set limit = 1 so that we

```
getdata <- function(x){
  coords <- as.numeric(x[c('minlon','minlat','maxlon','maxlat')])
  wkt <- wicket::wkt_correct(wicket::bounding_wkt(values = coords))
  num <- occ_search(geometry = wkt, limit = 1)$meta$count
  data.frame(
    city = x['city'],
    richness = num,
    stringsAsFactors = FALSE
  )
}</pre>
```

```
out <- apply(dat, 1, getdata)</pre>
```

Merge to original table

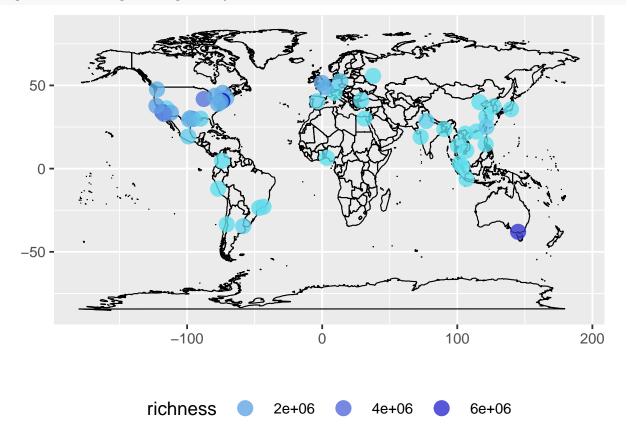

```
out <- merge(dat, ldply(out), by = "city")</pre>
```

Add centroids from bounding boxes

```
out <- transform(out, lat = (minlat + maxlat)/2, lon = (minlon + maxlon)/2)
```

 $Plot\ data$ 

```
mapp <- map_data('world')
ggplot(mapp, aes(long, lat)) +
  geom_polygon(aes(group=group), fill="white", alpha=0, color="black", size=0.4) +
  geom_point(data=out, aes(lon, lat, color=richness), size=5, alpha=0.8) +
  scale_color_continuous(low = "#60E1EE", high = "#0404C8") +
  labs(x="", y="") +
  theme_grey(base_size=14) +
  theme(legend.position = "bottom", legend.key = element_blank()) +
  guides(color = guide_legend(keywidth = 2))</pre>
```

 $_{
m 372}$  Valley oak occurrence data comparison

371

373

374

This example is inspired by a tweet from Antonio J. Perez-Luque who shared his plot on Twitter. Antonio compared the occurrences of Valley Oak (*Quercus lobata*) from GBIF to the distribution of the same species

- from the Atlas of US Trees.
- The data in question from the example above is no longer available, so below we use a different species.
- 377 Load libraries

```
library('rgbif')
library('raster')
library('sp')
library('sf')
library('rgeos')
library('rnaturalearth')
```

Get GBIF Data for Fraxinus excelsior

```
keyFe <- name_backbone(name = 'Fraxinus excelsior', kingdom = 'plants')$speciesKey
dat.Fe <- occ_search(taxonKey = keyFe, return = 'data', limit = 10000L)</pre>
```

379 Get Distribution map of F. excelsior European Forest Genetic Resources Programme

fe <- sf::read\_sf(file.path(tmp, "Fraxinus\_excelsior\_EUFORGEN.shp"))</pre>

From http://www.euforgen.org/species/fraxinus-excelsior/. And save shapefile in same directory

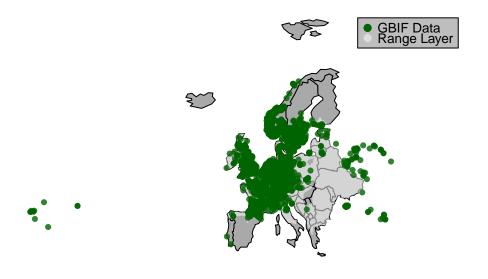

```
url <- 'http://www.euforgen.org/fileadmin/templates/euforgen.org/upload/Documents/Maps/Shapefile/Frax:
tmp <- tempdir()
download.file(url, destfile = "fraxinus_excelsior.zip")
unzip("fraxinus_excelsior.zip", exdir = tmp)</pre>
```

Get Elevation data of US

```
eur <- rnaturalearth::ne_countries(continent = "europe", type = "map_units")
eur1 <- eur[eur$sovereignt != "Russia", ]</pre>
```

Plot map

# **Distribution of Fraxinus excelsior**

#### 84 Conclusions and future directions

383

The rgbif, pygbif, and gbibrb libraries provide programmatic interfaces to GBIF's application programming interface (API) - a powerful tool for working with species occurrence data, and facilitating reproducible research. In fact, the rgbif package has already been used in more than 20 scholarly publications (as of 2020-02-25), including (Drozd & Šipoš 2013; Bartomeus et al. 2013; Barve 2014; Richardson et al. 2015; Feitosa et al. 2015; Collins et al. 2015; Malhado et al. 2015; Kong et al. 2015; Werner et al. 2015; Bone et al. 2015; Turner et al. 2015; Davison et al. 2015; Verheijen et al. 2015; Dellinger et al. 2015; Zizka Antonelli 2015; Janssens et al. 2016; Robertson et al. 2016; Amano et al. 2016; Butterfield et al. 2016).

The rgbif package is stable, and should not have many breaking changes unless necessitated due to

changes in the GBIF API. The pygbif and gbifrb libraries are in early development, and will greatly benefit from any feedback and use cases.

One area of focus in the future is to attempt to solve many use cases that have been brought up with respect to GBIF data. For example, some specimens are included in GBIF that are located in botanical gardens. For many research questions, researchers are interested in "wild" type occurrences, not those in human curated scenarios. Making removal of these occurrences easy would be very useful, but is actually quite a hard problem. There are many other problems like this, for which these three libraries will help in making more efficient and reproducible.
